

## **Basic Linux Commands**

ls (list)	<p><b>Use:</b> Shows files and folders in the current directory.</p> <p>ls ls folder ls -a (list all the hidden file and directories)</p>
cd (change directory)	<p><b>Use:</b> Move from one folder to another</p> <p>cd folder cd .. cd/folder1/folder2</p>
cat (concatenate)	<p><b>Use:</b> View content of a file</p> <p>cat file.txt cat folder1/folder2/file.txt</p>
pwd (print working directory)	<p><b>Use:</b> Shows current location/path</p> <p>pwd</p>
find	<p><b>Use:</b> Search for files and directories in the filesystem</p> <p>find &lt;path&gt; &lt;option&gt; &lt;value&gt; find -name file.txt find folder1 -name *.txt find folder1 -type d (find directory in folder1) find folder1 -size +10M (find files more than 10 MB) find folder1 -size -10M (find files less than 10 MB)</p>
wc	<p><b>Use:</b> Counts words inside file</p> <p>wc -l access.log (-l used for counting line inside a file)</p>
grep	<p><b>Use:</b> Search specific text/word inside files</p> <p>grep "word" filename grep hello file.txt grep "81.143.211.90" access.log (it finds entries the IP visited) grep -R "PRETTY_NAME" /directory/</p>

man (manual)	<p><b>Use:</b> It shows the official help/documentation of any Linux command inside the terminal.</p> <p>man ls man nmap</p>
--------------	--

## **Linux Operators**

**&** : Runs a command in the background so the terminal stays usable.

Example:

python script.py &

**&&** : Run multiple commands (if first succeeds)

Example:

mkdir test && cd test

**>** : Sends output of a command to a file and overwrites existing content.

Example:

echo hello > file.txt

**>>** : Adds output to end of a file without deleting old content.

Example:

echo hello >> file.txt

## **SSH**

SSH (Secure Shell) is a protocol used to securely connect to another computer/server over a network. It allows you to control a remote system through the terminal — safely and encrypted.

If a server is in another country, you don't need to go there physically. You can connect using SSH and control it from your laptop.

Example:

ssh user@192.168.1.10

ssh -p 2222 user@ip (connecting using port)

## Commands for filesystem

touch	<p><b>Use:</b> Create a new empty file</p> <p>touch file.txt</p>
<p>ls -l (size in bytes)</p> <p>ls -lh (size in MB/KB/GB) (human readable)</p>	<p><b>Use:</b> Shows detailed file info including permissions, owner, group</p> <p>ls -l</p> <p>ls -lh</p> <pre style="background-color: #2e3436; color: #eeeeec; padding: 10px;">tryhackme@linux2:~\$ ls -l total 16 -rw-r--r-- 1 user2      user2      14 May  5  2021 important -rw-r--r-- 1 tryhackme tryhackme   16 May  5  2021 myfile drwxr-xr-x 2 tryhackme tryhackme 4096 May  4  2021 myfolder -rw-r--r-- 1 tryhackme tryhackme   17 May  4  2021 unknown1 tryhackme@linux2:~\$ ls -lh total 16K -rw-r--r-- 1 user2      user2      14 May  5  2021 important -rw-r--r-- 1 tryhackme tryhackme   16 May  5  2021 myfile drwxr-xr-x 2 tryhackme tryhackme 4.0K May  4  2021 myfolder -rw-r--r-- 1 tryhackme tryhackme   17 May  4  2021 unknown1 tryhackme@linux2:~\$</pre> <p>-rw-r--r- → File permissions</p> <p>1 → Number of links</p> <p>user → Owner</p> <p>user → Group</p> <p>4096 → File size in bytes</p> <p>May 5 → Date</p> <p>important → File name</p>
su user	<p><b>Use:</b> switch user in Linux</p> <p>su user</p> <p>su -l user (after using -l, our new session has dropped us into the home directory of "user" automatically.)</p>

Permission format: `rw-rw-rw-`

This format is split into three groups:

Section	Applies To	Example
First 3	Owner	<code>rw-</code>
Next 3	Group	<code>rw-</code>
Last 3	Others	<code>rw-</code>

`r` → read

`w` → write

`x` → execute

Each permission has a numeric value:

Permission	Value
<code>r</code> (read)	4
<code>w</code> (write)	2
<code>x</code> (execute)	1

Common examples:

Symbolic	Numeric	Meaning
<code>rw-r-xr-x</code>	755	Owner can do everything, others can read and execute
<code>rw-r--r--</code>	644	Owner can read/write, others can only read
<code>rw-x-----</code>	700	Only the owner has access

Understanding numeric permissions is important because:

- Many Linux commands use numeric values (e.g. `chmod 755 file`)
- You can quickly identify security risks
- You can control who can access sensitive files

For example:

```
chmod 750 system_overview.txt
```

1. Owner: full access
2. Group: read + execute
3. Others: no access

## **Common linux directories**

<p>/etc (Editable Text Configuration)</p>	<p><b>Use:</b> Stores system configuration files</p> <p><b>Contains:</b></p> <ul style="list-style-type: none"><li>• user accounts</li><li>• passwords (hashed)</li><li>• service configs</li><li>• network configs</li></ul> <p><b>Example:</b></p> <ul style="list-style-type: none"><li>• /etc/passwd</li><li>• /etc/ssh/sshd_config</li></ul>
<p>/var (Variable data)</p>	<p><b>Use:</b> Files that change frequently</p> <p><b>Contains:</b></p> <ul style="list-style-type: none"><li>• logs</li><li>• cache</li><li>• mail</li><li>• web server data</li></ul> <p><b>Examples:</b></p> <ul style="list-style-type: none"><li>• /var/log → system logs</li><li>• /var/www → website files</li><li>• /var/mail → user mails</li></ul>

/root	<p><b>Use:</b> Home directory of root user (admin) Only root users can access it by default.</p> <p><b>Example:</b> /root</p> <p>This is like: /home/saif but for admin.</p>
/tmp (Temporary files)	<p><b>Use:</b> Stores temporary data created by programs</p> <ul style="list-style-type: none"> <li>• Anyone can access</li> <li>• Auto-deleted after reboot (usually)</li> </ul> <p><b>Example:</b> /tmp</p> <p><b>Used for:</b></p> <ul style="list-style-type: none"> <li>• temporary downloads</li> <li>• script output</li> <li>• testing</li> </ul>
/home	<p><b>Use:</b> Home folders of normal users</p> <p><b>Example:</b></p> <ul style="list-style-type: none"> <li>• /home/saif</li> <li>• /home/user2</li> </ul> <p>Each user stores personal files here.</p>
/bin	<p><b>Use:</b> Essential system commands (binary files)</p> <p><b>Examples:</b></p> <ul style="list-style-type: none"> <li>• /bin/ls</li> <li>• /bin/cp</li> <li>• /bin/mv</li> <li>• /bin/bash</li> </ul>

/usr	<p><b>Use:</b> Installed software &amp; user programs</p> <p><b>Examples:</b></p> <ul style="list-style-type: none"> <li>• /usr/bin</li> <li>• /usr/share</li> <li>• /usr/lib</li> </ul>
/dev	<p><b>Use:</b> Device files Represents hardware as files</p> <p><b>Examples:</b></p> <ul style="list-style-type: none"> <li>• /dev/sda → hard disk</li> <li>• /dev/null → black hole file</li> <li>• /dev/tty → terminal</li> </ul>
/opt	<p><b>Use:</b> Optional or third-party software</p> <p><b>Example:</b></p> <ul style="list-style-type: none"> <li>• /opt/google</li> <li>• /opt/lampp</li> </ul>
/boot	<p><b>Use:</b> Bootloader &amp; kernel files Needed to start Linux</p> <p><b>Example:</b></p> <ul style="list-style-type: none"> <li>• /boot/vmlinuz</li> </ul>

## **Terminal text editors**

**1. Nano:** nano is a simple terminal text editor in Linux.

**Example:** nano notes.txt

If file exists → opens it

If not → creates new file

**2. VIM:** advanced terminal text editor.

Used for:

- Editing configs
- Writing scripts
- Exploit development
- Server work
- CTFs & pentesting

Almost every Linux server has vim installed.

## **Downloading files**

wget = web get

Used to download files from the internet using a terminal.

Example:

wget URL

wget <https://example.com/file.txt>

wget -P /tmp -O saif.txt <https://example.com/test.txt>

wget reads options in order:

- -P /tmp → where to save
- -O saif.txt → rename file

So it will:

- download from URL
- save inside /tmp
- rename to saif.txt

## **SCP (Secure Copy Protocol)**

SCP is used to securely transfer files between computers over SSH.

Basic Syntax

scp [file] user@ip:/destination

Send file (your PC → remote machine)

scp file.txt user@192.168.1.10:/home/user/

Download file (remote → your PC)

```
scp user@ip:/path/file.txt .
```

. means current folder.

Copy entire folder

```
scp -r folder user@ip:/home/user/
```

-r = recursive (for folders)

Rule (VERY IMPORTANT)

SCP destination path must exist on the machine where the command is running.

If command runs on THM → path must be THM path

If command runs on Kali → path must be Kali path

## **Serving Files From Your Host (WEB)**

Hosting files from your own machine. So another machine (victim/THM/target) can download them via browser or wget.

Fastest method (Python web server)

Inside folder where file exists:

```
python3 -m http.server 8000
```

How target downloads file

From target machine:

```
wget http://YOUR-IP:8000/file.txt
```

## **Processes (Basic idea)**

A process is any running program on your system.

Each process has a unique PID (Process ID) assigned by Linux.

**ps command** (process Status)

Basic: ps

Shows processes of the current terminal session only.

All processes: ps aux

## **top command**

Use: top

Purpose: Real-time process monitor.

- Shows live:
- CPU usage
- RAM usage
- Running processes
- System load
- Updates continuously every few seconds

Press q or ^c to exit.

## **kill command**

Use: kill PID

Purpose: Stop/terminate a process using PID.

- Safely stops process
- Allows cleanup
- Recommended

## **Important kill signals**

1. SIGTERM (default): kill PID

- Safely stops process
- Allows cleanup
- Recommended

2. SIGKILL (force kill): kill -9 PID

- Force stop immediately
- No cleanup
- Use when process stuck

3. SIGSTOP (pause): kill -STOP PID

- Pauses process
- Can resume later

## Services & Boot Processes

Some programs run automatically when system starts:

- Web servers
- Databases
- SSH

Linux manages them using systemctl

### **systemctl Command**

Used to control services.

Start service: `sudo systemctl start apache2`

Stop service: `sudo systemctl stop apache2`

Check status: `sudo systemctl status apache2`

Enable service at boot: `sudo systemctl enable apache2`

Disable service at boot: `sudo systemctl disable apache2`

## **Background & Foreground Processes**

Processes run in two modes:

1. Foreground
2. Background

### Foreground Process

A foreground process runs directly in the terminal and blocks the terminal until it finishes.

Example: `echo "Hello Saif"`

Output shows immediately and the terminal waits until command finishes.

### Background Process

A background process runs without blocking the terminal.

You can continue using the terminal while it runs.

Run command in background:

Add & at end: `echo "Hi THM" &`

Output:

- Terminal returns process ID (PID)
- Command runs in background

Useful when:

- Copying large files
- Running scripts
- Scanning tools (nmap, etc)

### Why Background Processes Are Useful

Very important in hacking/linux:

- Run scans while doing other work
- Run servers (python http server)
- Reverse shells
- Long brute-force tools
- Automation scripts

Example: `python3 -m http.server 8000 &`

The server runs in the background while you use the terminal.

&	→	run in background
Ctrl+Z	→	pause/send background
bg	→	resume in background
fg	→	bring to foreground
ps aux	→	view processes

### Cron & Crontab

cron is a Linux background service (daemon) that runs scheduled tasks automatically.

Used for:

- Backups
- Running scripts
- Updates
- Automation
- Starting programs at specific time

Cron runs in the background after system boot.

crontab (cron table)

A special file that stores scheduled tasks (cron jobs).

- Each line = one scheduled task.
- The system reads this file and executes commands automatically at specified time.

Open crontab editor: **crontab -e**

\* \* \* \* \* command

```
GNU nano 4.8 /tmp/crontab.OUI4VJ/crontab
# Edit this file to introduce tasks to be run by cron.
#
# Each task to run has to be defined through a single line
# indicating with different fields when the task will be run
# and what command to run for the task
#
# To define the time you can provide concrete values for
# minute (m), hour (h), day of month (dom), month (mon),
# and day of week (dow) or use '*' in these fields (for 'any').
#
# Notice that tasks will be started based on the cron's system
# daemon's notion of time and timezones.
#
# Output of the crontab jobs (including errors) is sent through
# email to the user the crontab file belongs to (unless redirected).
#
# For example, you can run a backup of all your user accounts
# at 5 a.m every week with:
# 0 5 * * 1 tar -zcf /var/backups/home.tgz /home/
#
# For more information see the manual pages of crontab(5) and cron(8)
#
# m h dom mon dow command
0 */12 * * * cp -R /home/cmnatic/Documents /var/backups/ >/dev/null 2>&1
```

## **PACKAGES & SOFTWARE REPOSITORIES (APT)**

### **Package**

A package is a software/program in Linux

Example:

- firefox
- nmap
- nano
- apache

Linux installs software from repositories (repos).

### **Repository**

Repository is an online storage where Linux downloads software.

Its like App Store / Play Store for Linux

Ubuntu uses: apt (package manager)

Where repos are stored?

Main config location: /etc/apt/

Important files:

- /etc/apt/sources.list
- /etc/apt/sources.list.d/

These contain download sources.

### **Basic APT commands (VERY IMPORTANT)**

Update package list

- sudo apt update

Upgrade installed packages

- sudo apt upgrade

Install software

- sudo apt install nmap

Remove software

- sudo apt remove nmap

Search package

- apt search nmap

## How to add a repository

### EXAMPLE 1 — Install VLC (simple repo method)

Step 1: Add VLC repository

```
sudo add-apt-repository ppa:videolan/master-daily
```

Step 2: Update

```
sudo apt update
```

Step 3: Install VLC

```
sudo apt install vlc
```

Now VLC will install from the new repo.

### EXAMPLE 2 — Manual repository method (IMPORTANT)

Now we do the manual way (important for cybersecurity & exam).

We will add Brave browser repo.

Step 1: Go to repo folder

```
cd /etc/apt/sources.list.d/
```

Step 2: Create repo file

```
sudo nano brave.list
```

Paste inside:

```
deb [arch=amd64] https://brave-browser-apt-release.s3.brave.com/ stable main
```

Step 3: Add GPG security key

```
sudo curl -fsSL https://brave-browser-apt-release.s3.brave.com/brave-browser-archive-keyring.gpg
```

```
https://brave-browser-apt-release.s3.brave.com/brave-browser-archive-keyring.gpg
```

Step 4: Update system

```
sudo apt update
```

Step 5: Install

```
sudo apt install brave-browser
```

## Linux Logs

Logs = everything happening in the system.

Stored in:

/var/log

### 1. Authentication logs (LOGIN HISTORY)

/var/log/auth.log

Shows:

- SSH login
- sudo usage
- hacking attempts

Check:

cat /var/log/auth.log

### 2. System log

/var/log/syslog

Shows:

- System events & errors.

### 3. Apache logs (Web server)

/var/log/apache2/access.log

/var/log/apache2/error.log

Access log → who visited

Error log → errors

### 4. Fail2ban logs (attack blocking)

/var/log/fail2ban.log

### 5. Firewall logs

/var/log/ufw.log
